Abstract

Resveratrol was esterified with selected fatty acids to improve its lipophilicity and potential application in food and biological systems. In this study, resveratrol and monoesters of resveratryl propionate (RC3:0) and resveratryl docosahexaenate (RDHA) were examined for their effects on anti-inflammatory and anti-proliferative activity in vitro. All test compounds showed a decreased nitrite production in murine RAW 264.7 cells in a concentration dependent manner. Resveratrol, RC3:0, and RDHA were evaluated for their effects on cell viability using liver cancer (HepG2), colon cancer (HT-29, A431), breast cancer (MCF7), and gastric cancer (AGS) cell lines. All test compounds showed decreased cell viability of HepG2, A431, MCF7, HT-29, and AGS in a concentration-dependent manner. The results suggest that resveratrol esters may serve as potential anti-inflammatory and anti-proliferative agents.

Keywords: Resveratrol ester; Antioxidant activity; Anti-inflammatory activity; Anti-proliferative effect.

1. Introduction

Inflammation, such as redness, warmth, and swelling, is a normal reaction to injuries or infections. However, prolonged inflammation can progress further to various chronic diseases such as cardiovascular disease and cancer (Zhong et al., 2012). Reactive oxygen species (ROS) and reactive nitrogen species (RNS) may explain the link between inflammation and other chronic diseases (Wiseman and Halliwell, 1996). It is well known that ROS/RNS are continuously generated in vivo as a by-product of biological reactions (Halliwell, 1996, Fransen et al., 2012). Superoxide (O2•−), hydrogen peroxide (H2O2), and nitric oxide (ON•) are the primary ROS/RNS in a cell and they can readily form other ROS/RNS (Fransen et al., 2012). At a low level, ROS/RNS can serve as mediators for various biological responses such as gene expression and cell proliferation. However, at high levels, they can also cause harmful effects, including inflammation, cardiovascular disease, and cancer (Fransen et al., 2012; Zhong et al., 2012). Antioxidative defense systems in the body are frequently insufficient to keep ROS/RNS level in balance, therefore external sources of antioxidants are needed for this purpose (Yu, 1994; Loft and Poulsen, 1996).

Resveratrol is a powerful antioxidant and has been found in more than 70 plant species, especially grape skins. Red wine also contains resveratrol that originates from grapes (Dercks and Creasy, 1989). Resveratrol has received increasing attention since red wine was first shown to display cardioprotective effects (Baur and Sinclair, 2006). In addition, resveratrol prevents oxidation, cancer, coronary heart disease and inflammation (Jang et al., 1997; Wang et
Lipophilized resveratrol affects the generation of reactive nitrogen species

Oh et al., 2002; Donnelly et al., 2004). Although it has beneficial health properties, there are limitations to its bioactivity due to its hydrophilic nature and fast metabolism in the body (Zhong and Shahidi, 2011; Walle et al., 2004). Several studies on lipophilic derivatives of phenolic compounds, including resveratrol, have demonstrated their better performance in biological model systems. Acetylated resveratrol showed better inhibition of platelet activating factor (PAF; 1-O-alkyl-2-acetyl-sn-glycero-3-phosphocholine)-induced washed rabbit platelet aggregation and DU-145 human prostate cancer cell-growth than resveratrol itself (Fragopoulou et al., 2007; Cardile et al., 2005). In addition, Cichocki et al. (2008) reported that pterostilbene (dimethylated resveratrol) acted as an inhibitor of tumour promotion biomarker. In addition, Pan et al. (2007) reported that pterostilbene was able to inhibit cell proliferation and induce apoptosis in human gastric carcinoma cells. Moreover, esterification of resveratrol with polyunsaturated fatty acids (PUFAs) may provide a synergistic effect due to the individual bioactivities of its components. In addition, our preliminary data showed that some of the resveratrol esters had an effect on RNS generation in murine macrophages. For this reason, resveratrol was esterified with propionyl chloride (C3:0) and docosahexaenoyl chloride (DHA, C22:6), as described elsewhere (Oh and Shahidi, 2017). In this study, the mixture of R-3-O- and R-4′-O-monoesters (RC3:0 and RDHA) were evaluated for inhibition against NO production as well as anti-proliferative effect in various cancer cell lines.

2. Materials and methods

2.1. Materials

Resveratrol and DHA were acquired from DSM Nutritional Products (Columbia, MD, USA). The RAW 264.7 cells, derived from murine macrophages, were procured from the American Type Culture Collection (Rockville, MD, USA). Heat-inactivated fetal calf serum was purchased from Gibco (Grand Island, NY, USA). Lipopolysaccharide (LPS; Escherichia coli O127: E8, molecular weight, 60 kDa) was purchased from Sigma Chemical Co. (St. Louis, MO, USA). Human hepatocellular carcinoma (HepG2) cells (BCRC 60025) were procured from the Food Industry Research and Development Institute (Hsinchu, Taiwan). The human A431, AGS, and MCF7 cell lines were grown in DMEM supplemented with 10% heat-inactivated fetal calf serum, 100 units/mL of penicillin, and 100 μg/mL of streptomycin. Those cell lines were kept at 37°C in a humidified atmosphere of 5% CO₂.

2.2. Preparation of resveratrol esters

Preparation of resveratrol esters was the same as that previously described (Oh and Shahidi, 2017). Resveratrol was lipophilized with propionyl chloride and docosahexaenoyl chloride. The monoesters were identified by HPLC-MS and several types of NMR (¹H NMR, ¹³C NMR, COSY, HSQC, NOESY, and HMBC). Resveratrol and its esters (Figure 1) were subjected to NO production and cell viability assay evaluations.

2.3. Cell culture

The RAW 264.7 cells, derived from murine macrophages, were cultured in Dulbecco’s minimal essential medium (DMEM) containing 10% endotoxin-free, heat-inactivated fetal calf serum, 100 units/mL penicillin, and 100 μg/mL streptomycin. The AGS cell lines in DMEM-F12 were grown at 37 °C in 5% CO₂ atmosphere. HepG2, A431, and MCF7 cell lines were grown in DMEM supplemented with 10% heat-inactivated fetal calf serum, 100 units/mL of penicillin, and 100 μg/mL of streptomycin. Those cell lines were kept at 37°C in a humidified atmosphere of 5% CO₂.

2.4. Nitrite assay

The cells were seeded into 24 well plates, after reaching a density of 1×10⁶ cells/mL and were activated by changing their medium to serum-free DMEM without phenol red containing LPS (Zhong et al., 2012). The RAW 264.7 cells were treated with different concentrations of each compound and LPS or LPS alone for 24 h. The supernatants (100 μL) were mixed with the Griess reagent (1% sulphanilamide in 5% phosphoric acid and 0.1% naphthylethylenediamine dihydrochloride in water) in duplicate in 96-well plates. The absorbance was then read at 570 nm with an ELISA reader. Sodium nitrite (NaNO₂) was employed as a standard.

2.5. Cell viability of HepG2, A431, MCF7, HT-29, and AGS

Resveratrol and its esters were dissolved in dimethyl sulfoxide (DMSO). Cell viability of various cancer cell lines was assessed by using 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazoliumbromide (MTT) assay (Mosmann, 1983). The cells were plated at a density of 2×10⁵ cells/mL into 96 well plates and incubated for
3.1. Nitric oxide (NO) production

NO is an important molecule with known beneficial activities such as vascular relaxation and neurotransmission in mammals (Coleman, 2001). The solubility and diffusion properties of NO are similar to those of oxygen and it can freely cross cell membranes and has a long half-life (Coleman, 2001). It is a relatively stable free radical, however it can form peroxynitrite anion \((\text{ONOO}^-)\) which is a more reactive form of RNS (Kruidenier and Verspaget, 2002). Moreover, presence of an excessive amount of NO in activated immune cells leads to tissue damage during inflammation (Zhong et al., 2012). NO is generally synthesized from L-arginine by three different types of NO synthase (NOS), namely neural NO synthase (nNOS), endothelium NO synthase (eNOS), and inducible NO synthase (iNOS). Unlike nNOS and eNOS, iNOS is continuously active once expressed and produces NO at a sustained high level. Expression of iNOS can be induced by LPS or cytokines such as tumour necrosis factor (TNF)-\(\alpha\) and interleukin (IL)-1 (Coleman, 2001).

In this study, inhibition of LPS-induced NO production in murine RAW 264.7 was examined for two different resveratrol esters (Figure 1) and compared with resveratrol. The nitrite concentration in the culture medium was \(< 0.05\% \text{ (v/v)}\). MTT (100 \(\mu\)L) was added, and the cells were incubated for a further 1 h. Then the medium was aspirated and 100 \(\mu\)L of DMSO were added to dissolve the MTT-formazan crystals formed by metabolically viable cells. Cell viability was scanned with an enzyme-linked immunosorbent assay reader with a 570 nm filter.

24 h. The cells were then pretreated with test compounds at different concentration for 24 h. The final concentration of DMSO in the culture medium was \(< 0.05\% \text{ (v/v)}\). MTT (100 \(\mu\)L) was added, and the cells were incubated for a further 1 h. Then the medium was aspirated and 100 \(\mu\)L of DMSO were added to dissolve the MTT-formazan crystals formed by metabolically viable cells. Cell viability was scanned with an enzyme-linked immunosorbent assay reader with a 570 nm filter.

### 3. Results and discussions

3.2. Effect of resveratrol and its esters on the viability of HepG2, A431, MCF7, HT-29, and AGS cells

The effect of resveratrol and its esters at various concentrations on the viability of HepG2, A431, MCF7, HT-29, and AGS cells was determined by employing the MTT assay. As shown in Figure 3, resveratrol and its esters decreased the growth in cultured human cancer cells. Resveratrol at 5 \(\mu\)g/mL was able to decrease cell viability in all tested cancer cell lines except for A431 cells, whereas 5 \(\mu\)g/mL of RC3:0 showed cytotoxicity in all cancer cells. Concentration at 50-75 \(\mu\)g/mL, resveratrol decreased the cell viability less than 40% in HepG2, MCF7, HT29, and AGS, whereas RC3:0 showed less than 40% cell viability in HepG2, A431, MCF7, and AGS. RDHA at all concentrations showed the lowest cytotoxicity in HepG2, A431, HT29, and AGS cells compared to resveratrol and RC3:0. However, 50 and 75 \(\mu\)g/mL of RDHA in MCF7 cells showed no cell viability.

Several studies have demonstrated the anticancer activity of resveratrol and its derivatives. Jang et al. (1997) studied the anticancer activity of resveratrol in three major stages of carcinogenesis and found its chemopreventive effect due to acting as an antioxidant, antimutagen, anti-inflammatory, antiproliferation, and antiproliferation agent. In addition, resveratrol inhibited preneoplastic lesions in a mouse mammary glands culture model of carcinogenesis and inhibited tumorigenesis in a mouse skin cancer model. Pan et al. (2007) demonstrated that pterostilbene also possessed effects on cancer cells. They studied the inhibition of cell proliferation in pterostilbene treated human cancer cells such as COLO 205, AGS, HL-60, HepG2, and HT-29. They reported that pterostilbene (60 \(\mu\)M) showed the largest sensitive inhibitory effect on AGS cell-growth compared to the other cell tested. Patel et al. (2010) revealed the concentration of resveratrol and its metabolites in the colorectal tissue of cancer patients and the potential benefit of resveratrol as a chemopreventive agent in colorectal cancer. They found that daily doses of 0.5 or 1.0 \(\text{g} \text{ resveratrol could reduce cancer cell proliferation by 5\%. However, some studies have failed to show such anticancer activity. For example, Bove et al. (2002) found that resveratrol showed inhibitory effect on the growth of 4T1 breast cancer cell line (in vitro) in a dose- and time-dependent manner, however it showed no effect on the growth of 4T1 breast cancer in mice (in vivo). Baur and Sinclair (2006) suggested that this failure could be due to an inadequate dose of resveratrol, delivery method, and tumor origin. In pharmacokinetic perspective, resveratrol has extremely low bioavailability, and increasing the dose of resveratrol to overcome its low

![Figure 2. Effect of resveratrol and its monoesters on NO production in LPS-induced RAW 264.7 macrophages. RAW264.7 cells were treated with resveratrol, RDHA and RC3:0 different concentrations and LPS (100 ng/mL) for 24 h. Results were statistically analysed with one-way ANOVA followed by Tukey’s post-hoc test. Statistical significance, \(* P < 0.05\), **\(P < 0.01\) and ***\(P < 0.001\), compared with the LPS-treated group.](image-url)

bioavailability might not be possible due to toxicity. Therefore, lipophilised resveratrols need to be evaluated further in vivo for their anti-proliferative effect, which may ultimately lead to anti-cancer potential.

4. Summary

Two resveratrol esters demonstrated anti-inflammatory and anti-proliferative activities in this study. The test compounds were able to inhibit NO production in murine RAW 264.7 cells, suggesting their potential anti-inflammatory effect, which needs to be further investigated on the generation of iNOS protein, iNOS gene expression, the release of IL-6 and TNF-α. In addition, all test compounds were able to inhibit the generation of iNOS protein, iNOS gene expression, the release of IL-6 and TNF-α. In addition, all test compounds were able to inhibit the generation of iNOS protein, iNOS gene expression, the release of IL-6 and TNF-α. In addition, all test compounds were able to inhibit the generation of iNOS protein, iNOS gene expression, the release of IL-6 and TNF-α. In addition, all test compounds were able to inhibit the generation of iNOS protein, iNOS gene expression, the release of IL-6 and TNF-α. In addition, all test compounds were able to inhibit the generation of iNOS protein, iNOS gene expression, the release of IL-6 and TNF-α. In addition, all test compounds were able to inhibit the generation of iNOS protein, iNOS gene expression, the release of IL-6 and TNF-α.
