Abstract

Hull/seed coat contains various plant cells that are responsible for sustaining the life of seeds in which phenolics perform significant roles in supporting their functions. In the present study, inhibitory activities against the oxidation of LDL and DNA of soluble- and insoluble-bound phenolics in the dehulled and hull fractions of lentils were determined. In addition, their α-glucosidase inhibitory activity was also assessed. The hulls possessed much higher levels of phenolics in both the soluble- and insoluble-bound forms than dehulled grain fractions, and this led to their potent activities in suppressing the oxidation of LDL and DNA and inhibiting α-glucosidase activity. The high bioactivities of hulls might be due to the existence of various types of cells such as palisade and parenchyma cells containing numerous phenolics for sustaining their functions. This study may help in a better understanding of the localization of soluble- and insoluble-bound phenolics in the structure of lentil.

Keywords: Lentil; Seed coat; Phenolics; LDL oxidation; DNA scission.

1. Introduction

Lentils are valuable dietary sources of proteins, carbohydrates, minerals, vitamins, and dietary fiber (Rochfort and Panozzo, 2007). Moreover, they contain many health-promoting compounds such as phenolics, which are responsible for bioactivities such as anticancer and anti-hepatitis C virus (HCV), as well as reducing diabetes and cardiovascular disease (Hsu et al., 2015; Morgan et al., 2013; Narasimhan et al., 2015; Eitsuka et al., 2014; Mancuso and Santangelo, 2014).

In their structures, legumes mainly consist of hull/seed coat and dehulled grain parts. The hull fraction consists of several types of plant cells such as epidermis, hypodermis, chlorenchyma, palisade, parenchyma, and endothelium cells. These cells have various phenolic-containing organs such as vacuole and cell wall, thus the high level of phenolics in both soluble- and insoluble-bound forms are found in the hulls of legumes. On the other hand, the dehulled grain parts are primarily composed of the nutrition-storage cells such as the endosperm, hypocotyl and radicle, containing a high amount of lipids, proteins, and starch granules, leading to a low level of phenolics compared to the hulls (Figure 1).

Insoluble-bound phenolics are abundant in cereals, legumes, and seeds. They are responsible for the rigid structure of the cell wall by their association via covalent bonding to macromolecules such as cellulose, pectin, and structural protein. This association is through ether, ester, and covalent bonds. Cereals, legumes, and seeds contain a high proportion of insoluble-bound phenolics accounting for 20–60% of their total phenolics, while fruits and vegetables have a relatively lower concentration (7–38%) of insoluble-bound phenolics (Nayak et al., 2015; Sun and Cheng, 2002).

So far, the antioxidant potential of lentil cultivars such as free radical scavenging ability, metal chelation, and oxygen radical absorbance capacity (ORAC) has been well established in other studies, however, there is dearth information on the inhibitory activity of soluble- and insoluble-bound phenolics in lentils against oxidation of LDL cholesterol and DNA strand breakage. Therefore, this study evaluated and compared phenolic contents between the hulls and dehulled grains in lentil cultivars as well as assessing their α-glucosidase inhibitory activity.
2. Materials and methods

2.1. Materials

Lentils cultivars were provided by Professor Albert (Bert) Vandenberg of the experimental farm of the University of Saskatchewan, Saskatoon, SK, Canada. Organic solvents such as hexane, methanol, and acetone were purchased from Fisher Scientific Co. (Nepean, ON, Canada). Chemicals used for the antioxidant capacity and bioactivity such as Folin Ciocalteau’s reagent, gallic acid, and catechin were purchased from Sigma-Aldrich Canada Ltd. (Oakville, ON, Canada). Mono- and dibasic potassium phosphate, ferrous sulphate (FeSO₄), human low-density lipoprotein (hLDL), pBR 322 plasmid DNA, Tris acetate, agarose, bromophenol blue, glycerol, and xylene cyanol were obtained from Sigma-Aldrich Canada Ltd. SYBR safe gel stain was purchased from Probes Invitrogen (Eugene, OR, USA).

2.2. Dehulling of lentils

Lentils were cleaned thoroughly to remove any extraneous particles. Dehulling process employed was according to the procedure described by Chandrasekara et al. (2012).

2.3. Extraction of soluble phenolics (SPs) and insoluble-bound phenolics (IBPs)

The procedure followed for the extraction of SPs and IBPs was as described by Yeo and Shahidi (2020). Prior to the extraction, hulls and dehulled grains of lentils were defatted by using n-hexane. For the extraction of SPs, defatted hulls and dehulled lentils (1.0 g) was mixed with 10 mL of extraction medium composed of methanol/acetone/water (1:1:1, v/v/v), followed by 20 min of standing at room temperature. This procedure was repeated another two times more and the combined extracts were kept in one vial. The residue after extraction of SPs was used for the extraction of IBPs. Briefly, 1g of the residue was blended with 15 mL of 2M NaOH which was subsequently allowed to stand for 4h while stirring. The alkali hydrolyzed samples were mixed with 4.63 mL of 6 M HCl to reach pH < 2 for better extraction of the liberated phenolics. Subsequently, the released phenolics were extracted with ethyl acetate five times. After that, the solvent ethyl acetate was removed using a rotary evaporator, followed by dissolving in 10 mL of methanol.

2.4. Total phenolic content (TPC)

Total phenolic content of lentils was determined as described by Chandrasekara and Shahidi (2010) with minor modifications. An aliquot (125 μL) of each sample was mixed with 2 mL of distilled water and 63 μL of Folin-Ciocalteu reagent. Subsequently, the samples were allowed to react with 250 μL of 7% sodium carbonate and then kept in the dark for 30 min at ambient temperature. The absorbance of the final solution was read at 725 nm and expressed as mg gallic acid equivalents /g of DW.

2.5. Total flavonoid content (TFC)

Total flavonoid content of lentils was measured as described by Chandrasekara and Shahidi (2010) with slight modifications. An aliquot (125 μL) of each sample was mixed with 2 mL of distilled water and 63 μL of Folin-Ciocalteu reagent. Subsequently, the mixtures were allowed to react with 250 μL of 7% sodium carbonate and then kept in the dark for 30 min at ambient temperature. The absorbance of the final solution was read at 510 nm and expressed as mg catechin equivalents /g of DW.
2.6. Cupric ion-induced human low-density lipoprotein (LDL) peroxidation

The inhibitory activity of human LDL peroxidation induced by cupric ion was evaluated according to the method described by Alshikh et al. (2015). In order to remove EDTA dissolved in LDL cholesterol, LDL was dialyzed using 10 mM phosphate buffer (pH 7.4, 0.15 M NaCl) at 4 °C under a nitrogen blanket in the dark for 12 h. For assessing inhibitory activity against LDL oxidation, 0.8 mL of LDL cholesterol (0.04 mg mL/L) was used in a well-distributed model. The α-glucosidase (rat intestine) concentration (10 U/mL) was dissolved in 20 mM sodium phosphate buffer (pH 6.8). A phospholipid (P-SEP) solution was added to the mixture and incubated at 37 °C for 2 h. The conjugated dienes (CD) from LDL cholesterol was measured using a spectrophotometer (Agilent, Palo Alto, CA, USA).

2.7. Inhibition of peroxyl and hydroxyl radical-induced supercoiled DNA strand scission

Inhibitory activity against DNA strand scission induced by peroxyl and hydroxyl radicals of phenolics from lentils was measured according to the method described by Chandrasekara and Shahidi (2011). First, DNA strand (50 μg/mL), which was dissolved in 10 mM phosphate buffer (pH 7.4), was mixed with PBS (2 μL), pBR322 (50 μg/mL, 2 μL) and H2O2 (0.5 mM, 2 μL). The samples were mixed and incubated at 37 °C for 1 h for hydroxyl radical-induced oxidation. After incubation, 1 μL of 0.25% trypan blue, 0.25% xylene cyanol, and 50% glycerol) was blended with the reaction mixture. Then, 10 μL of the resultant solution was loaded onto 0.7% agarose gel solution (prepared in Tris–acetic acid–EDTA (TAE) buffer (40 mM Tris acetate containing 1 mM EDTA, pH 8.5), followed by the addition of SYBR safe (5 μL) into agarose gel solution (50 mL) as a gel stain. The analysis of electrophoresis was carried out using a model B1A horizontal mini gel electrophoresis system (Owl Separation Systems Inc., Portsmouth, NH, USA) and a model 300 V power supply (VWR International Inc., West Chester, PA, USA) in TAE buffer. The reading of intensity (area %) of bands was conducted using the Chemi-Imager 4400 software (Cell Biosciences).

2.8. α-Glucosidase inhibitory activity

α-Glucosidase inhibitory activity was determined according to Liu et al. (2011) with slight modification. The α-glucosidase (rat intestine) concentration (10 μU/mL) was dissolved in 20 mM sodium phosphate buffer (pH 6.8). In a test tube, 5 μL of α-glucosidase solution was mixed with 10 μL of phenolics and 620 μL of PBS, followed by pre-incubation at 37 °C in an oven for 15 min. The solution was mixed with 10 μL of phenolics and 620 μL of PBS, phosphate buffer (pH 6.8). In a test tube, 5 μL of α-glucosidase (rat intestine) concentration (10 U/mL) was dissolved in 20 mM sodium phosphate buffer (pH 6.8) by pre-incubation at 37 °C in an oven for 20 min. The mixture was allowed to react with 10 μL of 10 mM p-nitrophenyl-α-D-glucopyranoside (pNPG) solution and incubated at 37 °C for another 20 min. The reaction was terminated by adding 650 μL of 1 M Na2CO3, and absorbance was recorded at 410 nm.

2.9. Statistical analysis

The data from three independent replicates were subjected to one-way ANOVA. The mean was separated by Tukey’s HSD test (p < 0.05) using SPSS 16.0 for Windows (SPSS Inc., Chicago, IL, USA).

3. Results and discussion

3.1. Total phenolic content (TPC) and total flavonoid content (TFC)

Total phenolic content (TPC) was determined using Folin Ciocalteu’s reagent for lentil cultivars and the results were expressed as mg gallic acid equivalents (GAE)/g of DW (Table 1). In hulls, the range of TPC in SPs was 31.5–33.6 mg GAE/g and the corresponding IBPs were 19.7–24.3 mg GAE/g, showing a higher TPC of SPs than IBPs. On the other hand, the dehulled lentil grains showed significantly lower TPC values than the corresponding hulls of lentils. Thus, the soluble phenolics of dehulled grains was 1.6 mg GAE/g of DW in four lentil cultivars and 1.0–1.2 mg GAE/g in the insoluble-bound phenolics. This result indicates the biased distribution of phenolics in lentils. Therefore, both SPs and IBPs were more abundant in hulls than in the dehulled grains. This uneven distribution of phenolics has been well documented in pulses in the literature. For example, Das and Singh (2016) reported that maize possessed 282.5 μmol ferulic acid equivalent (FAE)/g of dried hulls, respectively, while a total of only 5.4 FAE/g was found in the endosperm. This supports the biased distribution of phenolics toward the hull portion than in the dehulled fraction in pulses. Some studies have shown a lower TPC in whole lentils than their hulls. For example, Alshikh et al. (2015) investigated TPC in whole seeds of six lentil cultivars and the range of TPC in SPs was 3.6–27.0 and 1.2–17.5 mg GAE/g DW in IBPs. Moreover, Xu and Chang (2008) reported that the range of TPCs in lentils was 4.9–9.6 mg GAE/g, which is lower than the TPC of hulls in the present study. These reports also support the biased distribution of phenolics toward hulls than in the dehulled grains of pulses.

Meanwhile, the ratios of IBPs to SPs in the hulls and dehulled grains of lentil cultivars were summarized in Table 1. This concept was first suggested in our previous study as an efficient indicator for the prediction of changes in the formation of phenolics from soluble into insoluble-bound form during germination (Ye and Shahidi, 2015). The range of this ratio was from 0.6 to 0.8 in four lentil cultivars in both hulls and dehulled grains, indicating that a high percentage of phenolics was present in the soluble form than in the insoluble-bound form in both hulls and dehulled grains of lentils.

Total flavonoid content of soluble- and insoluble-bound phenolics of four lentil cultivars showed a similar tendency to the total phenolic content (Table 1). Thus, the ranges of flavonoids as soluble- and insoluble-bound form were 1.1–1.2 and 0.7–0.9 mg CE/g in dehulled lentils, respectively, also showing a biased distribution of phenolics in the hulls than in the dehulled grain fraction.

Overall, phenolics were more abundant in hulls as shown in the total phenolic and total flavonoid contents. The dominance of phenolics to the hulls compared to the dehulled grains might be due to their physical structure and the difference in the composition of cells. As described in Figure 1, the hull fraction in grains consists of diverse types of cells such as palisade, hourglass, and parenchyma cells which have phenolic-containing organs such as vacuoles where most soluble phenolics occur and cell wall matrix having insoluble-bound phenolics. Conversely, a large portion of dehulled grain is filled with nutrition-storage organs such as endosperm. The endosperm is responsible for storing energy sources such as starch, proteins, and lipids and not the phenolic-containing organs such as vacuoles. Therefore, the different composition of...
3.2. Inhibitory activity of soluble- and insoluble-bound phenolics in hulls and dehulled grains of lentils tested.

The oxidation of LDL cholesterol in the bloodstream accelerates the accumulation of the proteoglycan-oxLDL complex at the arterial wall. This leads to a narrowing of the blood vessel and can cause cardiovascular disease. Thus, preventing the oxidation of LDL cholesterol is extremely important for reducing the incidence of vascular diseases. In the present study, we investigated the inhibitory activity of (insoluble-bound) phenolics in hulls compared to the corresponding dehulled grains of lentils. In both hydroxyl radical- and peroxyl radical-induced oxidation, hulls showed much higher inhibitory activity of phenolics in hulls and dehulled lentil grains than the corresponding dehulled grains, which strongly supports the results of the present study. Ranilla et al. (2007) also found that polyphenols of Brazilian and Peruvian Bean Cultivars (Phaseolus vulgaris L.) were present mainly in seed coat as compared to the cotyledon.

3.3. DNA scission inhibitory activities of soluble- and insoluble-bound phenolics in hulls and the dehulled lentil grains

The oxidation of DNA strand is responsible for the mutation of cells and can lead to serious adult diseases such as cancer. Thus, the oxidation of DNA strand should be prevented to maintain the health of the cells. In the present study, we investigated the inhibitory activities of soluble- and insoluble-bound phenolics in hulls and dehulled lentils against the oxidation of DNA strand, as summarized in Table 2. Figure 3 clearly shows the stronger inhibitory activity of (insoluble-bound) phenolics in hulls compared to the corresponding dehulled grains of lentils. In both hydroxyl radical- and peroxy radical-induced oxidation, hulls showed much higher inhibitory activity than the dehulled grains; namely, hulls showing 41–54% of inhibition in soluble phenolics and 58–65% of inhibition in insoluble-bound phenolics upon hydroxyl radical induce oxidation. On the other hand, dehulled grain fractions showed a

Values in each column having the same letter are not significantly different (p > 0.05).

LDL cholesterol performs a key function in transporting lipids to the cell body by acting as a shuttle. Nevertheless, they are referred to as “bad cholesterol” since they cause cardiovascular disease.

In the soluble phenolics of hulls, the absorbances of Greenland, 3494-6, Invincible, and Maxim were increased by 0.115, 0.099, 0.117, and 0.121 during the 11h of incubation, respectively, corresponding to 23, 22, 21, and 18% of inhibition against the oxidation of LDL cholesterol compared to the control (an increase of 0.149). In the same way, insoluble-bound phenolics in the hulls of lentils also attenuated the oxidation of LDL particles by 16–32% during LDL oxidation. On the other hand, the dehulled grains of lentils did not show any inhibitory activity against the oxidation of LDL cholesterol. This might be due to the difference in the level of phenolics in hulls and dehulled grains of lentils as discussed for TPC and TFC. Chandrasekara and Shahidi (2011) studied the inhibitory activities of hulls and dehulled grains of millets against the oxidation of LDL cholesterol and reported a better inhibitory activity of hulls than the corresponding dehulled grains, which strongly supports the results of the present study. Ranilla et al. (2007) also found that polyphenols of Brazilian and Peruvian Bean Cultivars (Phaseolus vulgaris L.) were present mainly in seed coat as compared to the cotyledon.

In the insoluble phenolics of hulls, the absorbances of Greenland, 3494-6, Invincible, and Maxim were increased by 0.115, 0.099, 0.117, and 0.121 during the 11h of incubation, respectively, corresponding to 23, 22, 21, and 18% of inhibition against the oxidation of LDL cholesterol compared to the control (an increase of 0.149). In the same way, insoluble-bound phenolics in the hulls of lentils also attenuated the oxidation of LDL particles by 16–32% during LDL oxidation. On the other hand, the dehulled grains of lentils did not show any inhibitory activity against the oxidation of LDL cholesterol. This might be due to the difference in the level of phenolics in hulls and dehulled grains of lentils as discussed for TPC and TFC. Chandrasekara and Shahidi (2011) studied the inhibitory activities of hulls and dehulled grains of millets against the oxidation of LDL cholesterol and reported a better inhibitory activity of hulls than the corresponding dehulled grains, which strongly supports the results of the present study. Ranilla et al. (2007) also found that polyphenols of Brazilian and Peruvian Bean Cultivars (Phaseolus vulgaris L.) were present mainly in seed coat as compared to the cotyledon.

3.3. DNA scission inhibitory activities of soluble- and insoluble-bound phenolics in hulls and the dehulled lentil grains

The oxidation of DNA strand is responsible for the mutation of cells and can lead to serious adult diseases such as cancer. Thus, the oxidation of DNA strand should be prevented to maintain the health of the cells. In the present study, we investigated the inhibitory activities of soluble- and insoluble-bound phenolics in hulls and dehulled lentils against the oxidation of DNA strand, as summarized in Table 2. Figure 3 clearly shows the stronger inhibitory activity of (insoluble-bound) phenolics in hulls compared to the corresponding dehulled grains of lentils. In both hydroxyl radical- and peroxy radical-induced oxidation, hulls showed much higher inhibitory activity than the dehulled grains; namely, hulls showing 41–54% of inhibition in soluble phenolics and 58–65% of inhibition in insoluble-bound phenolics upon hydroxyl radical induce oxidation. On the other hand, dehulled grain fractions showed a
relatively lower inhibitory activity against DNA oxidation than their corresponding hulls by displaying 20–44% inhibition in soluble phenolics and 32–52% in insoluble-bound phenolics. In the peroxyl radical-induced oxidation, similar trends were observed with a better inhibitory activity in hulls than the dehulled grains. Chandrasekara and Shahidi (2011) investigated the inhibitory activity of millet hulls and dehulled millets against oxidation of DNA strand; they reported a higher inhibitory activity of hulls than the corresponding dehulled grains, which agrees with the results of the present study.

In intracellular spaces, reactive oxygen species (ROS) are simultaneously produced at the mitochondria through Fenton’s reaction, and they perform an essential role by acting as a signalling molecule. However, the overproduction of ROS in cells can cause oxidative stress, thus leading to the oxidation of DNA. Therefore, dietary antioxidant supplementation has been suggested for maintaining the balance between ROS and antioxidants in the cells. In this regard, it is expected that lentils could serve as a suitable natural source of antioxidants.

3.4. α-Glucosidase inhibitory activity of phenolics in hulls and dehulled grains of lentils

α-Glucosidase is involved in the hydrolysis of polysaccharides into simple sugars, thus facilitating the supplement of energy to the cells. However, a high activity of α-glucosidase harms the patients who suffer from diabetes since the enzyme yields more sugar and increases the level of blood sugar in the patients. Therefore, the inhibition of enzyme activity of α-glucosidase is important for both reducing complications of the patients who are suffering type-2-diabetes and preventing the incidence of type-2-diabetes. The α-glucosidase inhibitory activities of soluble- and insoluble-bound phenolics in hulls and dehulled grains of lentils were measured and the results are shown in Figure 4. The soluble phenolics in hulls showed a much higher α-glucosidase inhibitory activity than the corresponding dehulled grains; soluble phenolics in hulls reduced 62–75% of its activity while dehulled grains did not inhibit α-glucosidase activity. Similar results were also found for the insoluble-bound phenolics; hulls of lentil cultivars attenuated α-glucosidase activity about 45-80% whereas dehulled grains did not show any inhibitory activity, except for Maxim (23%). Overall, hulls in both soluble- and insoluble-phenolics showed a higher α-glucosidase inhibitory activity than the corresponding dehulled grains. This might be due to the discrepancy in the localization of phenolics in the structure of lentils.

4. Conclusion

In the present study, antioxidant potentials of soluble- and insoluble-bound phenolics from hulls and dehulled grains of lentils and their other bioactivities were evaluated. In all measurements, hulls in both soluble- and insoluble-phenolics showed higher antioxidant and other bioactivities than the corresponding dehulled grains of lentils. The different composition of cells in hulls and dehulled grains might be a primary reason for the biased distribution of phenolics in the tested lentil cultivars. Thus, the hulls of lentil cultivars serve as an excellent source of soluble- and insoluble-bound phenolics and have the potential to serve as a source of nutraceutical and functional food ingredients.
